ABSTRACT:

This research presents the design and development of an Internet of Things (IoT) based water quality monitoring device that measures the Total Dissolved Solids (TDS) of drinking water in real time. Safe and clean drinking water is critical for human health, yet dissolved salts, minerals, heavy metals, and other impurities can remain even after household purification processes. Conventional laboratory testing methods provide highly accurate results but are slow, costly, and impractical for frequent everyday use, leaving households without continuous assurance of water safety.

To address this gap, the proposed system integrates an ESP32 microcontroller, a precise analog TDS sensor, a compact OLED display, and an active buzzer to create a compact, low-cost, and highly user-friendly solution suitable for domestic environments. The ESP32 reads analog signals from the TDS sensor, processes the data with efficient algorithms, and displays the measured TDS value on the OLED screen while simultaneously triggering an audible alert when the reading exceeds a pre-defined safe threshold. Power is supplied through a standard USB port or a portable power bank, eliminating the need for dedicated batteries and enabling continuous operation without interruption. The device utilizes open-source hardware and software, which makes it easily reproducible, modifiable, and scalable for larger community applications such as schools, small offices, and rural water supply points.

Extensive testing of the prototype demonstrated consistent and reliable detection of TDS levels across a variety of purified and municipal water samples, confirming its effectiveness as a practical household monitoring tool. By combining low-cost electronics, IoT principles, and real-time data visualization, this project offers an accessible, automated method to verify the effectiveness of domestic water purifiers, promote safe water consumption, and support public health initiatives. The system can be further enhanced for integration into smart-city infrastructure, remote monitoring platforms, or community-based early-

warning networks, ensuring continuous quality assessment and timely action against potential water contamination.

INTRODUCTION:

Access to clean, potable water is crucial for human health, well-being, and a high standard of living. Even with residential purifiers, the water may contain contaminants like dissolved salts, heavy metals, and chemical residuals. The accumulation of these substances poses serious health hazards, including kidney and digestive illnesses. High concentrations of Total Dissolved Solids (TDS) also impair flavor and cause scale buildup, reducing system efficiency and discouraging regular consumption. While specialized laboratory tests offer precision, they are too costly and time-consuming for routine home monitoring. Consequently, many users lack verifiable data, relying solely on the assumption that filtration guarantees safety. This highlights a critical need for an inexpensive, simple system that delivers constant, live information on water quality.

The Internet of Things (IoT) provides an efficient solution by enabling perpetual environmental tracking through intelligent, interconnected devices. Contemporary microcontrollers like the ESP32 are ideal, thanks to their built-in Wi-Fi, Bluetooth, dual-core processing, and low cost. This initiative presents an IoT-enabled system that uses a robust sensor to measure TDS levels. The output is displayed on a crisp OLED screen, and an active buzzer sounds an alarm when the water's safety level crosses a pre-established threshold. The apparatus is powered efficiently via a standard USB port or power bank, supporting uninterrupted service in homes, offices, or small organizations. Its open-source nature facilitates simple reproduction, modification, and scaling for larger implementations (e.g., rural distribution networks). By offering uninterrupted, immediate feedback, this device empowers consumers to verify purifier performance, encourages safer hydration, and illustrates the practical role of IoT in advancing public health and sustainable water management.

OBJECTIVES:

The core mission of this initiative is to design, engineer, and successfully implement a genuinely low-cost, real-time water quality monitoring system that is intuitive and highly accessible for widespread use in both individual households and small community settings. Specifically, the system is intended to precisely and reliably measure the Total Dissolved Solids (TDS) present in either purified or tap water, instantly converting this critical data into actionable safety feedback for the end-user, thereby significantly reducing potential long-term health risks.

A key set of objectives involves ensuring that the final device is compact, structurally robust, and easily portable, allowing for flexible operation without requiring complex, expensive laboratory infrastructure or specialized technical knowledge. From a technical perspective, the project focuses on the seamless integration of the powerful ESP32 microcontroller—leveraging its integrated processing and connectivity capabilities—to manage continuous sensor data, drive the visual output on a high-contrast OLED screen, and trigger an immediate, unmistakable audible buzzer alert whenever water quality crosses the predefined safety threshold. An important goal is to release the entire design as open-source, ensuring reproducibility and adaptability, which allows easy scaling for broader applications such as remote schools, corporate offices, or community water storage and distribution networks where continuous monitoring is currently unavailable.

By achieving these objectives, the project establishes a reliable operational framework designed to empower consumers with critical knowledge, promote healthier and safer consumption habits, and provide effortless verification of household purifier performance. This work effectively bridges the gap between infrequent professional laboratory testing and the daily need for continuous water safety assurance, ultimately contributing to improved public health awareness

and encouraging more sustainable and informed water management practices globally.

LITERATURE REVIEW:

The **Internet of Things (IoT)** represents a truly **transformative technology**, allowing for the sophisticated interconnection of physical devices, various sensors, and complex systems to **collect, process, and exchange continuous data in real-time**.

Over the last decade, the IoT paradigm has rapidly matured, transitioning from a largely theoretical framework into robust, practical applications spanning critical sectors like smart cities, agriculture, healthcare, and **environmental monitoring**. Its key technological advantages are rooted in **uninterrupted data acquisition**, powerful remote monitoring capabilities, process automation, and the fundamental ability to execute timely, **data-driven decisions**. Specifically for water quality assessment, IoT offers an unprecedented opportunity to decisively bridge the gap between traditional, time-consuming periodic laboratory testing and the immediate requirement for **ongoing, instantaneous feedback** on environmental and water conditions.

Previous, foundational research has already proven that dedicated IoT-enabled sensors can reliably track multiple water parameters, including acidity (pH), cloudiness (turbidity), temperature, and most importantly, **Total Dissolved Solids (TDS)**, to fully assess water safety. These smart systems are built around versatile microcontrollers that efficiently gather sensor data, perform the necessary local signal processing, and then transmit or display the results to end-users through interfaces such as **OLED screens** or specialized cloud dashboards. The strategic adoption of modern **wireless communication protocols** (like Wi-Fi) significantly

enhances both the accessibility and **scalability** of these essential monitoring systems.

Furthermore, the commitment to **open-source hardware and software** has successfully lowered the entry barrier, making highly reliable and customizable monitoring solutions economically viable for individual households, schools, and small-scale community systems. While real-time alerts and constant monitoring demonstrably enhance public awareness and mitigate health hazards by prompting timely corrective actions, designers must remain focused on persistent challenges such as accurate **sensor calibration**, long-term data reliability, and achieving optimal **power management** for sustained operation.

The literature clearly validates the substantial practical and educational value of a **compact, cost-effective, and user-friendly IoT system** specifically engineered to deliver immediate and critical feedback on TDS levels.

METHODOLOGY AND CONCEPT:

The primary concept of this project revolves around creating a compact, low-cost, and user-friendly IoT-based system that monitors the quality of drinking water in real time. The methodology is designed to combine both hardware and software components seamlessly, ensuring accurate measurement of Total Dissolved Solids (TDS) while delivering immediate, actionable feedback to the user. The system centers on the ESP32 microcontroller, chosen for its integrated Wi-Fi and Bluetooth capabilities, dual-core processing, and analog input channels, making it ideal for handling continuous sensor data and executing real-time computations.

A precise TDS sensor is employed to detect dissolved solids in water, and its analog output is converted into digital TDS readings by the microcontroller. These readings are displayed on a high-contrast OLED screen for easy visualization, while an active buzzer provides an audible alert when TDS levels exceed predefined safety thresholds. The methodology emphasizes simplicity and accessibility, with the entire device powered through a standard USB connection or a portable power bank, removing dependency on specialized batteries. During the design phase, careful attention is given to sensor calibration, ensuring consistent accuracy across different water sources, including tap, purified, or filtered water.

Software programming is executed using Arduino IDE, incorporating efficient algorithms to process analog data, convert it into meaningful TDS values, and manage both visual and audio alerts. The overall design is open-source, allowing for replication, customization, and potential scalability to larger applications such as community water tanks, schools, or office environments. Ergonomic considerations are also integrated into the methodology, ensuring the display is easily readable, the buzzer is clearly audible without being disruptive, and the device can be handled conveniently. By combining practical engineering principles with IoT technology, this methodology ensures a reliable, cost-effective, and intuitive water quality monitoring system, bridging

the gap between laboratory testing and daily household needs, while promoting health-conscious decisions and sustainable water management practices.

SYSTEM ARCHITECTURE:

(Block Diagramand Flow Description)

The architecture of this IoT-based water quality monitoring device is specifically engineered for the seamless, real-time integration of its hardware and software components. At its heart lies the **ESP32 microcontroller**, functioning as the central processing unit. Its primary responsibility is to continuously acquire data from the **TDS sensor**, process the raw analog signals, and manage all output mechanisms. The TDS sensor, which gauges the total dissolved solids in the water, transmits analog readings directly to the ESP32. Here, these signals undergo an **Analog-to-Digital Conversion (ADC)** and subsequent digital processing to calculate the accurate TDS value.

These processed readings are immediately presented to the user on a high-contrast **OLED screen**, offering a clear, visual indicator of the current water quality. Simultaneously, an **active buzzer** is integrated to provide an **immediate, audible alert** the instant TDS levels surpass a predetermined safety threshold, ensuring users are instantly notified of any potential contamination risk. Powering the system is simplified, utilizing a standard **USB connection or portable power bank**, which significantly eases deployment in various environments, including homes, small offices, or community settings.

The underlying software architecture encompasses routines for continuous data polling, real-time data processing, and threshold-based decision-making necessary to activate the buzzer alert. The overall data flow follows a clear, efficient sequence: **Sensor Data Collection → Signal Processing and TDS Conversion → Simultaneous Output to OLED Display and Buzzer**. This modular, open-source architecture promotes **easy maintenance, reproducibility, and customization**, allowing the system to be readily adapted and scaled for larger scenarios, such as community water tanks or institutional facilities. By

combining this straightforward data flow with a scalable design, the system guarantees efficient, user-friendly, and reliable water quality monitoring, effectively bringing laboratory-grade assurance to everyday use.

HARDWARE COMPONENTS AND SPECIFICATIONS:

The IoT-based water quality monitoring system relies on a carefully selected set of hardware components to ensure accuracy, reliability, and user-friendly operation. The core component is the ESP32 microcontroller, which features dual-core processing, integrated Wi-Fi and Bluetooth connectivity, multiple analog and digital input/output pins, and low-power operation modes, making it ideal for continuous sensor monitoring and real-time data processing. The Total Dissolved Solids (TDS) sensor is a high-precision analog device capable of measuring dissolved salts and minerals in water with an accuracy of ±5%, providing reliable readings for both purified and tap water. The sensor includes easy-to-connect terminals and requires minimal calibration for household use.

Visual feedback is provided by a 0.96-inch OLED display, which operates at 3.3V–5V, offers high contrast for clear readability, and supports I2C communication with the microcontroller for seamless integration. An active piezo buzzer is incorporated to deliver audible alerts when TDS levels exceed the predefined safety threshold, ensuring that users receive immediate notification of potential water quality issues. The system is powered via a standard USB connection or a portable power bank, eliminating the need for dedicated batteries and supporting uninterrupted operation in various settings. Additional components include male-to-female and female-to-female jumper wires for flexible connections, and, if required, a small breadboard for temporary prototyping. Each component is chosen for its low cost, ease of availability, and compatibility with the ESP32 platform. The combination of these hardware elements ensures that the system is compact, portable, and simple to assemble, while maintaining high accuracy and durability. By leveraging widely available, low-power, and

cost-effective hardware, the project delivers a scalable and user-friendly water quality monitoring solution that can be implemented in households, schools, offices, or small community water distribution networks, providing continuous, real-time insight into the effectiveness of water purifiers and overall water safety.

SOFTWARE DESIGN AND SOURCE CODE:

The IoT-based water quality monitoring system's software architecture focuses on delivering a seamless, efficient, and user-centric experience. Built on the Arduino IDE, the system leverages the ESP32 microcontroller's capabilities and extensive library support to integrate sensors, manage displays, and control peripherals. Key software components include data collection, signal refinement, display management, and alert systems.

The data collection module continuously reads analog output from the TDS sensor, converting raw signals into digital values representing TDS concentrations in parts per million (ppm). Signal refinement involves calibration, averaging, and threshold comparison to ensure accurate and stable readings. A user-friendly OLED display, interfaced via I2C, provides real-time TDS level visualization, accompanied by clear indicators for safe or unsafe water quality.

An active buzzer is triggered when TDS readings exceed predefined safety limits, ensuring prompt notification. The system incorporates error handling and safeguards to manage sensor disconnections or invalid readings, guaranteeing reliable operation. The modular code structure allows for easy adaptability and future enhancements, such as integrating additional sensors or connecting to cloud platforms for remote data analysis.

This software design enables autonomous operation, immediate feedback, and sustained accuracy, making the system accessible to users with minimal technical expertise. By combining robust data handling, intuitive visuals, and reliable alerts, the IoT-based water quality

monitoring system offers a practical solution for household or community use.

display.println(" ppm");

  // Trigger buzzer if water quality is bad (example threshold)
if(tdsValue> 500) {
digitalWrite(BUZZER_PIN, HIGH);
  } else {
digitalWrite(BUZZER_PIN, LOW);
  }

display.display();
delay(1000);
}
```

USER-CENTRIC DESIGN AND ERGONOMICS:

(Easeof Use, Interface Design)

User-centric design and ergonomic principles were established as **fundamental criteria** for guaranteeing that the IoT water quality monitoring system is **intuitive, practical, and broadly accessible**, making it usable even for individuals who lack specialized technical expertise. The physical device itself is intentionally built for **simplicity and discretion**, featuring an **ultra-compact form factor** that is ideal for effortless placement on busy kitchen counters, positioned strategically near existing purification systems, or easily integrated within modest community installations.

Central to the user interface is the **OLED display**, which offers high-contrast visual output, clearly presenting the crucial **TDS readings in parts per million (ppm)**. This clarity is further enhanced by **simple, graphical visual indicators**—specifically **color-coded thresholds**—that enable users to instantly and unambiguously discern safe, moderate, or critically unsafe water conditions at a glance.

Supplementing this visual feedback, an **active buzzer** provides an essential, **high-priority audible alert feature**, immediately notifying users if the measured TDS levels breach the established safety limits, which ensures critical information is conveyed even when the user is not directly viewing the display unit. Setup and power management are deliberately streamlined for convenience: all internal wiring and external connections are securely organized to prevent accidental

disconnections during use, and the device is powered efficiently via a **standard USB connection or any portable power bank**.

This crucial decision eliminates the need for complex, proprietary, or fixed power infrastructure. Ergonomics guided meticulous design choices related to the device's **minimal weight, comfortable handling, and overall structural durability**, ensuring it is convenient for regular user interaction, relocation, and transport. Furthermore, the system's underlying software interface is entirely **self-explanatory**, automatically providing continuous real-time updates and automated alerts without requiring any manual user calibration or intervention.

This dedicated focus on **continuous, automated monitoring** significantly promotes user convenience and directly encourages the routine verification of water safety. By effectively blending clear visual indicators and immediate audible alerts with a simple, robust hardware design, the system rigorously prioritizes **user accessibility**, ensuring the transformative benefits of IoT monitoring reach the widest possible audience, thereby promoting healthier, informed consumption habits and establishing an **indispensable, practical, everyday tool** for safeguarding public health across diverse domestic and community settings.

IMPLEMENTATION AND TESTING:

The implementation of the IoT-based water quality monitoring system involved assembling the selected hardware components, configuring the software environment, and performing comprehensive testing to ensure reliable operation.

Hardware assembly began with connecting the ESP32 microcontroller to the TDS sensor, OLED display, and active buzzer using male-to-female and female-to-female jumper wires, ensuring all power, ground, and signal connections were secure.

The OLED display was mounted to provide clear visibility, while the buzzer was positioned to emit audible alerts effectively. Once hardware assembly was complete, the Arduino IDE was used to upload the source code to the ESP32, enabling real-time data acquisition, processing, and output.

Testing was carried out in multiple stages, beginning with verifying sensor readings using different water samples, including tap water and purified water, to confirm the TDS sensor's accuracy and consistency.

The display was monitored to ensure correct visualization of readings, while the buzzer functionality was validated by testing threshold limits, confirming that alerts triggered appropriately when TDS levels exceeded predefined safe values. Additional tests included assessing the system's response time, stability during continuous operation, and durability under normal household conditions.

Calibration was performed to refine the conversion of analog readings into accurate TDS values in parts per million, ensuring reliable measurement across different water sources. The system was also evaluated for ease of setup and usability, confirming that minimal technical knowledge is required for operation. The successful implementation and testing demonstrated that the device reliably

measures water quality, displays readings clearly, and provides immediate alerts, fulfilling the project's objectives.

The testing phase also highlighted the system's potential for scalability, as its modular design allows integration with additional sensors or IoT platforms for remote monitoring.

Overall, the implementation and testing process validated the functionality, accuracy, and user-friendliness of the system, confirming its practical application as a cost-effective, real-time water quality monitoring solution suitable for household and community use.

COST ESTIMATION AND ECONOMIC FEASIBILITY:

Component	Quantity	Unit Cost (₹)	Total Cost (₹)	Remarks
ESP32 Development Board	1	400-600	600	Dual-core, Wi-Fi, multiple I/O pins
TDS Sensor	1	400–600	600	Measures total dissolved solids accurately
OLED Display (0.96 inch)	1	200	200	High-contrast real-time visualization
Active Piezo Buzzer	1	100–150	150	Audible alert for unsafe water
JumperWires, Connectors	1 set	100–180	180	For flexible connections and prototyping
Total Estimated Cost	**-**	**-**	**1730**	-

RESULTS AND OUTCOMES:

(Performance Data, TDS Ranges)

The IoT-based water quality monitoring system was thoroughly tested using various water samples, including purified drinking water, tap water, and untreated well water, to evaluate accuracy, response time, and reliability.

During these trials, the TDS sensor consistently provided real-time readings that closely matched reference TDS meters, confirming its suitability for everyday use.

The OLED display successfully showed live TDS values in **parts per million (ppm)**, while the buzzer activated immediately whenever the TDS level crossed the predefined safety threshold, ensuring that users could identify unsafe water without constantly observing the display.

Testing revealed stable operation over extended periods, with negligible drift in sensor readings and a quick response time of just a few seconds after sample changes. The system maintained accurate measurement across a wide range of TDS values typically found in domestic water supplies.

Below is a **sample TDS range table** based on the testing results and commonly accepted standards:

Water Type	TDS Range(ppm)	Quality Indicator
Distilled / RO Water	**0 - 50**	**Excellent / Pure**
Purified Drinking Water	**50 - 150**	**Very Good / Safe**
Tap Water (Urban)	**150 - 300**	**Acceptable for Consumption**
Hard Water	**300 - 500**	**Poor Taste, Long-Term Risk**
Contaminated Water	**>500**	**Unsafe for Drinking**

These results confirm that the system can clearly distinguish between safe and unsafe water conditions, offering users reliable and actionable data. The combination of a real-time OLED display and buzzer alert ensures that even non-technical users can interpret the readings instantly. Overall, the testing validates the device as a **low-cost, high-impact solution** for household and small community water quality monitoring.

SUSTAINABILITY AND SCALABILITY:

The system is designed to be both **eco-friendly** and easily expandable.

- **Sustainability:** Uses low-power ESP32 microcontroller with deep-sleep modes to reduce energy consumption. Components like the TDS sensor and OLED display are durable, low-cost, and replaceable, minimizing electronic waste. Open-source design allows easy local repairs and upgrades.
- **Scalability:** Modular architecture supports adding more sensors (pH, turbidity, temperature) without major redesign. Built-in Wi-Fi/Bluetooth enables future features such as cloud data logging and mobile alerts. Suitable for households, schools, offices, and larger community networks.

This balance of efficiency, flexibility, and affordability ensures long-term relevance and adaptability in diverse environments.

LIMITATIONS AND CHALLENGES:

Despite its effectiveness, the system has a few key constraints:

- **Sensor Sensitivity:** TDS readings can vary slightly due to temperature, water flow, or sensor calibration.
- **Power Dependency:** Requires a steady power supply or rechargeable battery for continuous monitoring.
- **Environmental Factors:** Extreme humidity or dust can affect sensor lifespan and accuracy.
- **User Maintenance:** Periodic cleaning and calibration of the TDS sensor are essential for reliable results.

Addressing these limitations through hardware upgrades and firmware improvements will enhance system reliability and functionality in future versions.

GOVERNMENT SCHEMES & POTENTIAL SUPPORT:

Multiple government programs and international frameworks offer crucial support for projects dedicated to enhancing water quality monitoring and public health outcomes. In India, the **Jal Jeevan Mission** serves as a key initiative, aiming to provide safe and reliable drinking water to all rural homes; this TDS monitoring system directly supports its mission of verifying water safety at the consumer level. Similarly, the now-restructured **National Rural Drinking Water Programme (NRDWP)** provides resources and technical backing for rural water purification and monitoring efforts.

For urban deployment, the **Atal Mission for Rejuvenation and Urban Transformation (AMRUT)** actively promotes smart city infrastructure, creating a direct pathway for integrating IoT-based water monitoring technologies. Furthermore, the **Swachh Bharat Mission** drives demand for clean water practices and sanitation solutions, establishing a receptive environment for affordable, decentralized water testing systems.

From a business perspective, the **Startup India** and **Make in India** initiatives offer substantial advantages, including financial incentives, tax benefits, and incubation support specifically targeting innovative, domestically developed IoT and environmental solutions.

Globally, major organizations like **UNICEF** and the **World Health Organization (WHO)**, alongside the **UN Sustainable Development Goal 6 (SDG 6)** (Clean Water and Sanitation), provide avenues for international grants, funding, and partnerships. Strategically leveraging these diverse national and global schemes can significantly **reduce deployment costs, accelerate market adoption**, and ensure the widespread use of real-time water quality monitoring solutions.

FUTURE WORK AND DEVELOPMENT ROADMAP:

The project holds significant potential for enhancement and large-scale deployment in the future. Key development directions include:

- **Mobile App Integration:** Creating a dedicated Android/iOS application to display TDS readings, alert notifications, and historical water quality data in real time.
- **Cloud Data Storage:** Enabling IoT cloud connectivity (such as Firebase or AWS) to store long-term water quality records for analysis and trend prediction.
- **Multi-Parameter Monitoring:** Expanding the system to measure additional parameters like pH, turbidity, temperature, and dissolved oxygen for a complete water quality profile.
- **Solar-Powered Operation:** Incorporating renewable energy options to make the system self-sustainable in remote or rural areas.
- **AI-Based Prediction:** Using machine learning algorithms to predict potential water contamination risks based on sensor data patterns.
- **Mass Production and Cost Optimization:** Refining the design for large-scale manufacturing to reduce production costs and improve affordability.
- **Government and NGO Collaboration:** Partnering with public health departments and NGOs for deployment in rural villages, schools, and disaster-affected regions.

This roadmap ensures the project can evolve from a prototype to a fully scalable, globally deployable water monitoring solution.

CONCLUSION:

This project successfully demonstrates the design and implementation of a low-cost, real-time water quality monitoring system using an ESP32 microcontroller, TDS sensor, OLED display, and buzzer alarm. The system effectively measures Total Dissolved Solids (TDS) levels in drinking water and provides instant visual and audible feedback, ensuring users can quickly identify unsafe water quality.

By leveraging IoT technology, it bridges the gap between traditional laboratory testing and the daily need for continuous monitoring, offering a compact, portable, and user-friendly solution.

The project not only improves public awareness about water safety but also promotes healthier consumption habits by providing accurate, actionable data at the household or community level.

With open-source design principles, it allows easy replication, customization, and scaling for broader applications such as schools, offices, and rural water systems.

Ultimately, this initiative represents an important step toward sustainable water management and public health improvement, proving that accessible technology can empower communities and support long-term environmental safety.
